**Purpose:** Evaluate 2 papaya box samples “Kirkland” and “New World Farms” for basis weight of components, Edge crush test (ECT) and estimation of % recycle fiber content.

**Background:**
A fundamental strength property of shipping boxes is the edge crush test which is usually related linearly to the basis weight of the components comprising the corrugated board. More strength per unit basis weight is achieved when using virgin rather than recycled pulp. The fraction of recycled pulp in this project is estimated on the basis of comparative microscopic images and counting the individual fibers according to various classifications. The standard comparison is made to a microscopic image of a known 100% virgin linerboard. Recycled fibers are those that are not expected to be found in a furnish and fibers that appear to be fragmented or fibrillated from mechanical defibering action in the repulping process.

**About IPST Paper Analysis Laboratory:**
*Paper Testing at IPST has over 2800 square feet of lab space dedicated to address any paper, board, and specialty product testing needs in areas of strength, optical, surface, and structural properties. In addition to conventional TAPPI method testing capabilities, the Paper Testing group can provide special services in the areas of environmental simulations and accelerated aging. Environmental chambers cover high and low temperature and humidity conditions. Unique capabilities include precision paper grinding or sheet splitting to produce specific thickness sections, score cracking of linerboards, needle abrasion testing to predict relative slitter and knife blade wear caused by abrasive components in both base sheet and coating materials, nondestructive in-plane and out-of-plane (Z-directional) ultrasonic testing, optical 3D Moiré surface topography for the measurement of curl or cockle. Our labs also offer the latest automated capabilities for real time hygroexpansive response measurements, and horizontal plane static and kinetic coefficient of friction determinations. Humidity and temperature Tests, reports and services of IPST@GT are confidential and advisory, and cannot be quoted without specific permission.*
conditions are monitored and tracked continually to ensure proper standard TAPPI conditions of
23°C and 50 % RH.

Data from the IPST Paper Analysis Laboratory have been validated through IPST participation
in the Collaborative Testing Services Inc., and PAPRICAN Paper and Pulp Monitor programs.
Internal checks by comparison of selected samples with their historic data and regular
instrument calibrations using standards are standard procedures. This ensures that the
equipment, methods and results are consistent with correct industry practice.

Methods:
Standard Tappi methods are used in most tests unless otherwise specified. Measurements consist
of 6 or more repeats per sample.

Basis weight of components - 9 x 12 inch samples were weighed to 3 decimal places,
soaked in water, he layers peeled apart then equilibrated at 20% RH to dry and followed by
conditioning at 50% RH then weighed. C flue was assumes with a take up factor of 1.43 for the
medium actual length in the calculation of grams per unit area.

Edge Crush Test – samples were cut using a Billerud cutter for the horizontal edges 2 x 2”
and tested using method T 839 with an L&W compression tester, 10 readings per sample were
made.

% Recycle estimation - Graff C stain is applied to microscopy slides prepared from
disintegrated pulp. 122 milligrams of each sample component was disintegrated into 100 ml of
water using a Waring Blender at medium speed for 40 seconds. 4 0.11 drops are placed of each
such pulp slurry on a microscopy slide and stained with Graff C stain. Unbleached kraft shows
up as yellow bleached kraft shows as gray. The assumption is made that virgin corrugated board
consists of unbleached softwood kraft fibers that would appear several millimeters long without
fibrillation or fragments indicating mechanical repulping action. Magnification of 40X is used
for general observation and fiber counting, 100X and 400 X is used for specied identification
when required. Comparison of test slides with slides prepared from 100% virgin bleached

Tests, reports and services of IPST@GT are confidential and advisory, and cannot be quoted
without specific permission.
softwood kraft show indicate that an average count of 153 long fibers can be expected in a standard slide scanning count. Therefore, the % recycle is based on one of 2 formulas:

1) If long fiber counts > 153, % Recycle = \{1 - \text{(bleached kraft count}/\text{total fiber count})\} \times 100 

2) If long fiber counts < 153, meaning some of the long fibers have been fractured:
   \% Recycle = \{1 - \text{long fiber count/153 + kraft count/153}\} \times 100

**Data:**

Most measurements consist of at least 6 repeats or more whenever possible.

A comparison of significant differences between samples can be gleaned through comparison of the results with error bars representing the 95% confidence intervals of the results from repeated measurements for each sample. Values with overlapping error bars cannot to be considered to be statistically significant.

**Table 1. Summary of the testing results. The “c.i.” are 95% confidence intervals for each corresponding average value.**

Figure 1. Stained microscopy shot 40X of virgin unbleached kraft pulp showing pine softwood fibers. This is the slide used for comparison purposes to estimate the % recycle content in other samples.

Figure 2. Kirklund single face white top liner microscopy shot 100X showing long pine softwood fibers (White or Scots pine from the pitting pattern) and a hardwood (yellow poplar) bleached kraft vessel. White tops are usually made from bleached hardwood kraft for superior coating and graphics printability.

Tests, reports and services of IPST@GT are confidential and advisory, and cannot be quoted without specific permission.
Figure 6. Birch hardwood vessel detail 400 X found in the Kirkland double face sample. Bleached kraft appears as gray when stained with Graff C and is considered as a recycling contaminant in corrugated board components which ideally consist of virgin unbleached softwood fibers. In this case, this vessel appears relatively intact and is considered here as virgin for the white-top.
